

# A 2D Shortest Superstring (Tile Canvas) Problem: Exact Models and an Ant Colony Optimization Heuristic

Tran Thanh Dat

September 24, 2025

## Abstract

We study a 2D analogue of the Shortest Superstring problem. Given a set of  $T$  square tiles of size  $n \times n$  over a finite alphabet, the task is to place one translated copy of each tile on an integer grid so that overlapping cells agree and the side length  $m$  of the bounding canvas is minimized. We present: (i) a precise problem statement; (ii) an exact Mixed-Integer Linear Programming (MILP) model solved iteratively over  $m$ ; (iii) a complete brute-force backtracking oracle for small instances; and (iv) a practical Ant Colony Optimization (ACO) heuristic with sparse pheromones, overlap-based heuristics, and compactness bias. The formulations match the provided construction paradigm (edges encode relative placements), and the ACO is designed to scale for  $n < 10$  and moderate  $T$ .

## 1 Problem definition

Let  $\mathcal{T} = \{1, \dots, T\}$  be tile indices. Each tile  $t \in \mathcal{T}$  is an array  $A^{(t)} \in \Sigma^{n \times n}$  over a finite alphabet  $\Sigma$  (e.g.,  $\{0, 1\}$ ). A placement assigns to each tile  $t$  an integer top-left offset  $p_t = (x_t, y_t) \in \mathbb{Z}^2$ . The induced canvas labeling is

$$C(X, Y) = A^{(t)}(X - x_t, Y - y_t) \quad \text{for any } (X, Y) \text{ covered by tile } t,$$

which must be *well-defined*: whenever two tiles cover the same cell, they must agree:  $A^{(u)}(i, j) = A^{(v)}(i + \Delta x, j + \Delta y)$  for all overlapping indices. The (axis-aligned) bounding box of a placement is

$$[X_{\min}, X_{\max}] \times [Y_{\min}, Y_{\max}] \quad \text{where } X_{\min} = \min_t x_t, X_{\max} = \max_t (x_t + n - 1), \text{ etc.}$$

We define the *canvas side*  $m = \max\{X_{\max} - X_{\min} + 1, Y_{\max} - Y_{\min} + 1\}$ , and aim to minimize  $m$ .

**Decision** Given  $m \in \mathbb{Z}_{\geq n}$ , does there exist a conflict-free placement with bounding square contained in  $[0, m - 1]^2$ ? The optimization task is to find the minimal feasible  $m$ .

## 2 Exact models

### 2.1 Iterative MILP feasibility (Gurobi)

For a fixed  $m$ , each tile must be placed at a top-left integer coordinate  $(x, y) \in \{0, \dots, m - n\}^2$ . Introduce binary variables

$$p_{txy} = \begin{cases} 1 & \text{if tile } t \text{ is placed at } (x, y), \\ 0 & \text{otherwise.} \end{cases}$$

**Assignment constraints** Each tile placed exactly once:

$$\sum_{x=0}^{m-n} \sum_{y=0}^{m-n} p_{txy} = 1 \quad \forall t \in \mathcal{T}. \quad (1)$$

**Pairwise conflict constraints** For any two tiles  $u < v$  and placements  $(x, y), (x', y')$ , if the two translated tiles overlap at any cell with different symbols, forbid selecting both:

$$p_{uxy} + p_{vx'y'} \leq 1 \quad \text{for all conflicting pairs.} \quad (2)$$

Conflicts are precomputed in  $O(n^2)$  per pair of placements by checking the intersection of their  $n \times n$  supports.

The model has  $T \cdot (m - n + 1)^2$  binaries. We iterate  $m = n, n + 1, \dots, \bar{m}$  (with a simple upper bound like  $\bar{m} = n \lceil \sqrt{T} \rceil$ ) and solve (1)–(2) for feasibility. The first feasible  $m$  is optimal.

## 2.2 Brute-force backtracking oracle

For small  $n$  and moderate  $T$ , an exact search over placements is practical. For each  $m$  from  $n$  upward:

- (i) Enumerate the domain  $\{0, \dots, m - n\}^2$  for every tile.
- (ii) Backtrack with MRV (place the tile with the fewest currently feasible positions), using a hash-based occupancy to test conflicts in  $O(n^2)$  per attempt.
- (iii) Order candidate positions by descending current overlap with the partial canvas to find solutions quickly.

This exactly matches the feasibility decision and returns optimal  $m$  at the first success.

---

### Algorithm 1 Greedy Overlap Insertion (GOI)

---

**Require:** Tiles  $\mathcal{T}$  ( $n \times n$ ), TopK feasible offsets with  $ov > 0$

```

1:  $L \leftarrow \{(r, 0, 0)\}$ ;  $P \leftarrow \{r\}$ ;  $U \leftarrow \mathcal{T} \setminus \{r\}$ ; init BBox
2: while  $U \neq \emptyset$  do
3:    $\text{Best} \leftarrow \text{None}$ 
4:   for all  $v \in U$  do
5:      $\mathcal{C}_v \leftarrow \{(x_u + dx, y_u + dy)\}$  from  $u \in P, (dx, dy) \in \text{TopK}(u, v)$ 
6:     if  $\mathcal{C}_v = \emptyset$  then add perimeter candidates
7:     end if
8:     for all  $(x, y) \in \mathcal{C}_v$  do
9:       if placing  $v$  at  $(x, y)$  is conflict-free then
10:         $H \leftarrow \sum_{u \in P} ov(u, v, x - x_u, y - y_u)$ 
11:         $\Delta m \leftarrow$  enlargement if  $v$  placed at  $(x, y)$ 
12:        update  $\text{Best}$  by max  $H$ , tie-break min  $\Delta m$ 
13:      end if
14:    end for
15:  end for
16:  if  $\text{Best} = \text{None}$  then break
17:  end if
18:  place  $\text{Best}$  into  $L$ ; update BBox; move  $v^*$  from  $U$  to  $P$ 
19: end while
20: return  $L, m(L)$ 
```

---

---

**Algorithm 2** Greedy Lowest Enlargement Insertion (GLEI)

---

**Require:** Same inputs as GOI

```
1: init  $L, P, U, \text{BBox}$  as before
2: while  $U \neq \emptyset$  do
3:    $\text{Best} \leftarrow \text{None}$ 
4:   for all  $v \in U$  do
5:     build  $\mathcal{C}_v$  as in GOI (TopK + perimeter if needed)
6:     for all  $(x, y) \in \mathcal{C}_v$  do
7:       if conflict-free then
8:          $\Delta m \leftarrow$  enlargement of canvas side
9:          $H \leftarrow \sum_{u \in P} \text{ov}(u, v, x - x_u, y - y_u)$ 
10:        update  $\text{Best}$  by min  $\Delta m$ , tie-break max  $H$ 
11:       end if
12:     end for
13:   end for
14:   if  $\text{Best} = \text{None}$  then break
15:   end if
16:   place  $\text{Best}$ ; update  $\text{BBox}$ ; move  $v^*$  from  $U$  to  $P$ 
17: end while
18: return  $L, m(L)$ 
```

---

### 3 ACO heuristic (constructive layout)

We cast construction as repeatedly adding an unplaced tile at an absolute coordinate. Fix tile  $r$  at  $(0, 0)$  to break translation symmetry. Let  $P$  be the set of placed tiles with positions  $p_u = (x_u, y_u)$  and  $U$  the unplaced set.

#### 3.1 Sparse relative moves

For each ordered pair  $(u, v)$ , we precompute *feasible offsets*  $\Delta = (\Delta x, \Delta y)$  with  $|\Delta x|, |\Delta y| \leq n - 1$  such that, when  $v$  is placed at  $p_u + \Delta$ , all overlapping cells match. We score each by the consistent overlap count  $\text{ov}(u, v, \Delta)$  and retain only the top- $K$  offsets (typically  $K \in [8, 64]$ ) to sparsify the move space. These define a sparse pheromone tensor  $\tau[u, v, \Delta]$ .

#### 3.2 Heuristic and pheromone aggregation

When considering placing  $v$  at absolute position  $(x, y)$ , each placed  $u \in P$  implies a relative offset  $\Delta_{u \rightarrow v} = (x - x_u, y - y_u)$ . We define

$$\begin{aligned} \text{Heuristic}(v, x, y) &= \sum_{u \in P} \eta(u, v, \Delta_{u \rightarrow v}), \quad \text{where } \eta(u, v, \Delta) = \text{ov}(u, v, \Delta) \text{ if feasible, else } 0, \\ \text{Phero}(v, x, y) &= \sum_{u \in P} \tau[u, v, \Delta_{u \rightarrow v}], \\ \text{Comp}(v, x, y) &= \exp(-\lambda \Delta \text{BBox}(v, x, y)), \end{aligned}$$

with  $\Delta \text{BBox}$  the increase in the bounding box's larger side from adding  $(v, x, y)$ . The sampling weight is

$$w(v, x, y) = (\text{Phero}(v, x, y))^\alpha \cdot (\text{Heuristic}(v, x, y) + \epsilon)^\beta \cdot (\text{Comp}(v, x, y))^\gamma. \quad (3)$$

### 3.3 Candidate generation

Rather than scanning all  $(x, y)$ , we propose a small set per  $v$ :

- For each  $u \in P$  and each retained  $\Delta \in \text{TopK}(u, v)$ , propose  $(x, y) = p_u + \Delta$ .
- Deduplicate and keep only conflict-free positions (checked in  $O(n^2)$  via occupancy).
- If a  $v$  receives no proposals, add a small set of perimeter positions just outside the current bounding box (allows bridging disconnected components).

This yields  $O(|P| \cdot K)$  proposals per  $v$ .

### 3.4 Pheromone updates

We record a parent edge  $(u^*, v, \Delta^*)$  per placement, where  $u^*$  maximizes  $\eta(\cdot)$  at the chosen  $(x, y)$ . After an ant completes a solution with canvas side  $m(\mathcal{S})$ , we perform evaporation and reinforcement:

$$\tau \leftarrow (1 - \rho)\tau, \quad \tau[u^*, v, \Delta^*] \leftarrow \tau[u^*, v, \Delta^*] + \frac{Q}{m(\mathcal{S})}. \quad (4)$$

An additional elitist boost on the global-best layout improves stability.

### 3.5 Pseudocode

---

**Algorithm 3** Sparse-ACO for 2D Tile Canvas Minimization

---

**Require:** tiles  $A^{(t)}$ , size  $n$ , parameters  $K, \alpha, \beta, \gamma, \lambda, \rho, Q$

- 1: Precompute  $\text{TOPK}(u, v)$  and overlaps  $\text{ov}(u, v, \Delta)$  for  $|\Delta| \leq n - 1$ ; init  $\tau = \tau_0$  on retained entries.
  - 2: **for** iteration = 1.. $I$  **do**
  - 3:   **for** ant = 1.. $N$  **do**
  - 4:      $P \leftarrow \{r\}$  with  $p_r \leftarrow (0, 0)$ ; init occupancy; record parent-edges  $E \leftarrow \emptyset$ .
  - 5:     **while**  $|P| < T$  **do**
  - 6:        $\mathcal{C} \leftarrow \emptyset$  ▷ candidate moves
  - 7:       **for** each  $v \notin P$  **do**
  - 8:          Propose positions from  $\{p_u + \Delta : u \in P, \Delta \in \text{TopK}(u, v)\}$ ; add perimeter fallbacks if none.
  - 9:          **for** each feasible  $(x, y)$  for  $v$  **do**
  - 10:            Compute  $H = \sum_{u \in P} \eta(u, v, \Delta_{u \rightarrow v})$ ,  $T = \sum_{u \in P} \tau[u, v, \Delta_{u \rightarrow v}]$ ,  $c = \exp(-\lambda \Delta \text{BBox})$ .
  - 11:            Add  $(v, x, y)$  to  $\mathcal{C}$  with weight  $w = (T^\alpha)(H + \epsilon)^\beta (c^\gamma)$ .
  - 12:          **end for**
  - 13:       **end for**
  - 14:       Sample one  $(v^*, x^*, y^*) \in \mathcal{C}$  by normalized weights; place  $v^*$ ; update occupancy and bbox.
  - 15:       Record parent  $(u^*, v^*, \Delta^*)$  with maximal  $\eta$ .
  - 16:     **end while**
  - 17:      $m \leftarrow$  final canvas side; evaporate  $\tau \leftarrow (1 - \rho)\tau$ ; reinforce edges in  $E$  by  $Q/m$ .
  - 18:   **end for**
  - 19:   Optionally reinforce global-best edges (elitist).
  - 20: **end for**
-

### 3.6 Complexity and practical settings

Per construction step, candidate generation is  $O(|P| \cdot K)$ ; each feasibility check is  $O(n^2)$ , so overall roughly  $O(T \cdot |P| \cdot K \cdot n^2)$  per ant per iteration (typically modest for  $n < 10$ ). Recommended defaults:  $K = 16\text{--}32$ ,  $\alpha = 1$ ,  $\beta \in [2, 4]$ ,  $\gamma = 1$ ,  $\lambda \in [0.01, 0.05]$ ,  $\rho = 0.1$ ,  $Q \approx n^2$ .

## 4 Implementation notes

**Exact solvers.** The MILP feasibility model (Section 2.1) solves to optimality by increasing  $m$ . A backtracking oracle (Section 2.2) provides an independent ground-truth for very small instances.

**Heuristic.** The ACO uses a sparse pheromone tensor on only the best pairwise offsets, drastically shrinking the move space. Perimeter fallback proposals let ants connect components even when pairwise overlaps offer no guidance.

## 5 Extensions

- **Rotations/reflections:** expand tiles by distinct transformed copies; include orientation in  $(u, v, \Delta)$ .
- **Non-square alphabets / multi-channel:** treat channels independently for feasibility; overlaps sum across channels.
- **Post-compaction:** a fast greedy left/up compaction after construction often reduces  $m$  further without changing consistency.
- **Lower/upper bounds:**  $m \geq \left\lceil \sqrt{|\cup_t \text{supp}(A^{(t)})|} \right\rceil$ . Trivial upper bound  $m \leq n \lceil \sqrt{T} \rceil$  (grid packing).

## 6 Summary

We formalized the 2D tile canvas minimization problem, presented two exact methods (MILP and backtracking) for ground-truth, and detailed a scalable ACO with strong overlap-aware heuristics and compactness bias. The approach closely follows the “edge as relative placement” construction you outlined, while remaining practical for  $n < 10$ .
